## IEEE 802.11be Multi-Channel Operation

- IEEE 802.11be
  - Next-generation IEEE 802.11 standard project after IEEE 802.11ax
  - App requirements of high throughput, low latency and high reliability
- Multi-Channel Operation
  - Emergence of dual-radio end user devices (STAs) and tri-band Access Points (APs)
  - Data from same traffic session over multiple channels using first available channel
- Asynchronous operation
  - By default, independent medium access on each channel with simultaneous transmission and reception over multiple channels

## STR Capability

- STR: simultaneous transmission and reception over a pair of channels
- STR capability
  - Ability to support reception on one channel while transmitting on other channel
  - Depends on RF design and operation parameters including channel location, bandwidth of each channel, antenna distribution, etc.
- AP is always STR capable
  - Typically many-antenna systems and selects the channels of operation
  - Otherwise, negligible gain from multi-channel operation

#### Non-STR STAs

- STAs may lack STR capability due to smaller form factor and simpler design
- Indicate capability to AP dynamically based on operation parameters
- Example: two channels on 5 GHz band

## Challenging Scenarios with non-STR STAs

- Reception failure at non-STR STA
  - AP and non-STR STA transmit to each other
  - Non-STR STA fails to receive

Channel A

AP to STA 1

BUSY

STA 1

Channel B

BUSY

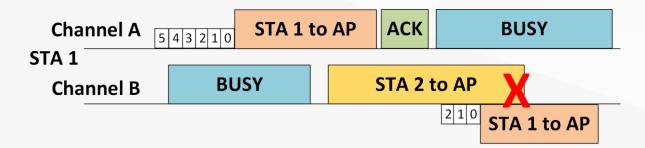

10

STA 1 to AP

- Deafness Issue
  - Non-STR STA completes transmission on Channel A
  - o Fails to detect ongoing transmission on Channel B
  - Collision at AP impacting other STAs' performance

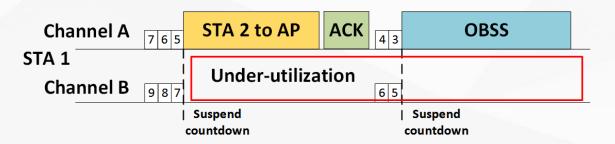

STA 1: Non-STR STA

**STA 2**: other STA

#### **Conservative Baseline Solution**

- Prevention of reception failure at non-STR STAs
- Procedure at non-STR STA
  - Suspend backoff countdown on Channel A when in receive state on Channel B
- Procedure at AP
  - o Do not transmit to any non-STR STA when receiving an intra-BSS frame

STA 1: Non-STR STA,

STA 2: single link STA

BSS: AP's network

**OBSS: Neighboring BSS** 

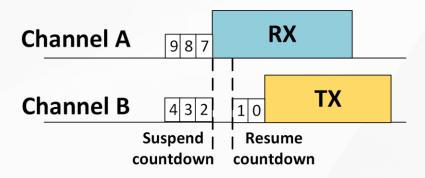

Medium under-utilization by non-STR STA and deafness issue not addressed

#### Contributions

To maximize the multi-channel medium utilization of non-STR STAs, we propose Constraint Aware Asynchronous multi-channel operation (CA- ASYNC)

- Opportunistic Backoff Countdown Resumption
  - o Protocol to identify suitable scenarios and resume medium access
- Multi-Channel Busy Status Feedback
  - o Protocol to prevent non-STR STA transmission during intra-BSS reception at AP
- Fair Transmission Opportunity Aggregation
  - Simultaneous uplink multi-channel transmission with fairness consideration
- Using custom ns-3 simulator, we analyze CA-ASYNC's performance

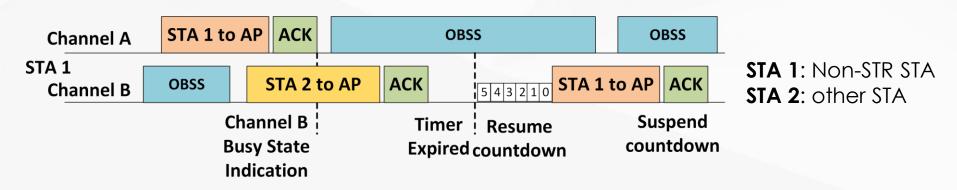

## Opportunistic Backoff Countdown Resumption

- Objective: To help non-STR STA determine with minimum delay if it can resume backoff countdown on Channel B after switching to busy state on Channel A
- BSS Color, UL/DL flag in IEEE 802.11ax PHY header
- STA identifier in PHY header
  - In DL, backoff countdown resumed if STA ID does not match non-STR STA's ID
  - o In UL, AP can transmit to other STAs on other channels instead of this non-STR STA

## Multi-Channel Busy Status Feedback

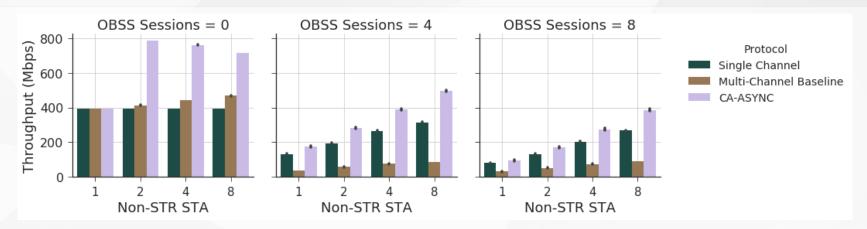

- Non-STR STA is "deaf" on Channel B after its transmission on Channel A
- Objective: To prevent non-STR STA's transmission on Channel B if there is an ongoing transmission in the BSS
- Proposal
  - If AP is currently receiving intra-BSS frame on Channel B, AP indicates Busy Status in feedback to non-STR STA on Channel A
  - Non-STR STA suspends medium access on Channel B until the earliest event between receiving an intra-BSS frame or pre-defined countdown expiry

#### Performance Evaluation

- Implemented CA-ASYNC and alternative strategies in ns-3 simulator
- Network model
  - Single AP operating a two-channel BSS with varying number of non-STR STAs
  - o Each channel occupies 80 MHz
  - Effective data rate of 400 Mbps on each channel including overhead
  - Varying number of single channel STAs and OBSS traffic flows
- Traffic model
  - o To isolate non-STR STA medium utilization, focus on uplink traffic
  - Full-buffered traffic generated at each non-STR STA
  - Non-STR STA uses obtained channel access for 5.5 ms of data transmission
  - o OBSS traffic flow uses channel access for a random duration up to 5 ms
- Over 100 separate runs of 10 seconds in network time per configuration

#### **CA-ASYNC's Medium Utilization**

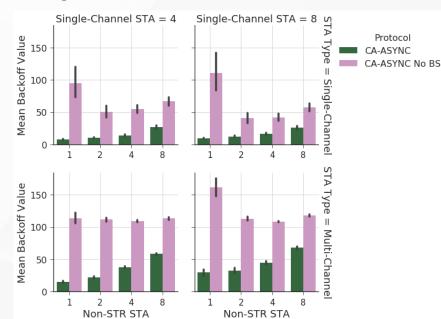

- No OBSS traffic case
  - With single non-STR STA, only one channel used at a time
- Multi-channel baseline
  - Contention deferred on all channels when a channel is busy due to other traffic
  - Leads to worse performance than even single channel operation
- CA-ASYNC gain
  - Contention resumed by non-STR STA on identifying OBSS or intra-BSS uplink transmission or downlink transmission not for itself

## CA-ASYNC's Busy Status Feedback

 Transmission failure => doubling of 802.11 contention and backoff counter value chosen randomly from the bigger range

- CA-ASYNC No BSF = CA-ASYNC without Busy Status Feedback protocol
- The mean backoff value of single channel STAs as well as non-STR STAs is significantly lower for CA-ASYNC including Busy Status Feedback

#### Conclusion and Future Work

- Multi-channel operation is a key feature of next-generation IEEE 802.11be
- New challenges introduced by non-STR STAs
- Proposed CA-ASYNC protocol to improve medium access opportunities for non-STR STAs and eliminate non-STR STA deafness problem

- Several topics for further research including
  - Simultaneous downlink transmissions to non-STR STAs
  - Protection mechanisms for multi-channel operation
